

type-checking a spacetime

Maximilian Weinhold

June 2026

1 Introduction

We first mention decidability f , which is universally undefined for *sufficiently* complex proofs, as Turing's construction showed. I regret C. Shannon will not be showing, if only because we imagine a light type-check¹ with a basement entropic production.

Rudely, as all tenements of the halting problem show— if we ask always f ?
– We do not resolve on an answer².

As for the program in question Δp , it is a simple *typeNS* we have configured in a very specific way: $typeNS := check(\delta), \delta, \delta, check(\delta), \delta, \delta \dots$ where we say check every third instance and the check holds two side of NS as $bly = \nu$ and resolves each separately and equates the products.

The problem of the Navier-Stokes Existence and Smoothness I propose is one of:

Error : decidable($f; f \in \{bly \otimes \nu\}$)

As in if we include *check* as an instance of perturbation on a puncta-type δ and thus consider it unresolved *not* δ . So

And check error exception as? $\Delta p(check(\delta), \delta, \delta, check(\delta), \delta, \delta \dots) \rightarrow not \delta$ as off-chain.

¹Most of the time your type-check is unnoticed

²More or less precisely, the Halting Problem is a cast by every program and set of rules. That *Stop* and *continuous while-loop* is equivalently returned, or a contradiction. For every program simulatable as a Turing machine, the absolute encapsulment of all the ticker tape cannot, by a single machine, be immediately gleaned on a single ticker tape its halt. Every program stops or does not in its own way
