

tis and the Navier-Stokes

Maximilian Weinhold

June 2026

1 Introduction

The inviscid spheres was a title that popped into my head while researching the Navier-Stokes. The energetic response that would complete a flow-field was complete. However, and not a fault of perception, the outcome was wrong.

First associating $\lim_{x \rightarrow \infty} := 0$

and $\forall x; *(x \notin \{\infty\}; f(x) = \alpha$ for x at a truncated runtime $*$ (and the class containing infinity of a check character (Me¹, powerpoint 2026).

and let $x \in U$.

Hold category check for *settling*/13.

Infinitely resolvable under conditions presented for reductive (continuously differentiable) *alpha*.

Realized as such: parameterize *settling*.

Undecidable.

Notable as changing Gödel number?

Or Kolmogorov if we may associate the complete state of the Navier-Stokes with a program and assuming $Kol(\infty) > Kol(1)$ ² The square to the $Kol(1)$ does nothing but reveal.

¹max *.s*.weinhold@gmail.com

²The author notes a $Kol(1)$ steady process is vulnerable to a bit-flip, or is ambivalent since no average potential exists. This is an aside, but I actually think $Size\{Kol(1)\}$ is quite a large number.
